SOURCES OF RESISTANCE TO THE SWEETCLOVER APHID
IN INTRODUCED SPECIES OF MELILOTUS 1/

CURRENT SERIAL RECORDS

By G. R. Manglitz, Entomology Research Division,
and H. J. Gorz, Crops Research Division

The possibility of locating sources of resistance to the sweetclover aphid (Theroaphis riehmi (Börner)) and of controlling this insect with resistant varieties of sweetclover has been discussed previously (3).^{2/} This report describes screening tests with introduced species of Melilotus^{3/} and evaluation of sweetclover aphid resistance in selections made from these species.

Methods

Screening was accomplished by planting the test species of Melilotus in rows in greenhouse flats. Each flat also contained two rows of a susceptible check--common biennial yellow sweetclover--and one row of a resistant check--N-13, a large-seeded strain previously shown to be the best source of resistance available (3). Several additional checks were planted in some flats. The plants were grown in a greenhouse section, where an uncaged culture of the aphids was maintained, so that the seedlings became infested shortly after emergence. The first stand count was made soon after plant emergence and a final count when most of the susceptible check plants had been killed by the aphids. Individual plants that appeared to be resistant were potted and held for further testing.

Further evaluation of the selected plants was made by confining three first- or second-instar nymphs on each plant. When the plants were examined at 3-day intervals, three additional nymphs were added if all the nymphs in the cage were dead. Aphid counts were made at the end of 2 1/2 weeks.

1/ Cooperative study with the Nebraska Agricultural Experiment Station. Published with the approval of the Director as Paper No. 1392, Journal Series, Nebraska Agricultural Experiment Station. Contribution No. 237 of the Department of Entomology, University of Nebraska, Lincoln.

2/ Numbers in parentheses refer to Literature Cited at the end of this report.

3/ Seed furnished through the courtesy of W. H. Skrdla, U.S. Department of Agriculture, Regional Plant Introduction Station, Ames, Iowa.

Selfed seed was obtained from each plant, and the seedling progeny were evaluated for resistance under conditions similar to those when the initial selections were made.

Results

None of the 98 accessions tested were uniformly resistant, but 26 of them appeared to contain one or more resistant plants. The performance of the individual accessions, when subjected to mass aphid infestation, is given in tables 1 and 2. The following accessions had survival rates approaching or exceeding that of the resistant check N-13: P.I. 31647, 204898, 228351 of M. officinalis, P.I. 52916, 187005, 202041 of M. alba, and P.I. 67512 of M. taurica. However, aphid damage was severe, and few resistant plants were found in most of these accessions. Presumably the greater survival rates of these accessions resulted from increased seedling vigor or some other factor increasing tolerance to aphid attack. Because high levels of either antibiosis or nonpreference resistance were available, no selections were made for higher survival rates unless injury was greatly reduced.

It is evident that resistance was available in introductions from many different countries of the world, as shown in table 3. A high proportion of the selections were of Turkish origin, but the percentage of resistant plants in the Turkish accessions was not high, with the exception of P.I. 178985. The resistant check N-13 was previously selected, in mass, for large seed from P.I. 178985 and thus should have been equivalent to P.I. 178985 in resistance. Approximately half of the plants in the resistant check entries were resistant to the aphid. This is similar to the situation reported in the literature (1,2) concerning resistance to the spotted alfalfa aphid (Theroaphis maculata Buckton) in alfalfa, where alfalfa varieties with Turkistan parentage have a higher proportion of resistant plants than most other varieties tested. In both alfalfa and sweetclover, sources of aphid resistance appear to be greatest in the geographical area of probable origin of the plant species.

In table 4, sources of resistance are considered in relation to species of Melilotus. Nearly one-third of the accessions of both M. officinalis and M. alba produced one or more resistant plants, but the 19 accessions of 9 additional species produced only 3 resistant selections. This is consistent with results of other workers (4), who reported much variation in aphid reaction within M. alba and M. officinalis.

Of the 51 plants selected, only 35 survived transplanting, and selfed-seed was produced on only 20. Results of the antibiosis and progeny tests on the selected plants are shown in table 5. Only selections 51 and II-11-2 appeared susceptible in the antibiosis test, indicating misidentification of resistance in the original selections. The former was not progeny tested and the latter produced all susceptible progeny. Selections 49, 134-1, and II-40-5 appeared resistant in the antibiosis test, but produced all susceptible progeny. Of the other 16 selections that were progeny tested, 2 had all resistant progeny whereas the remainder appeared to be segregating, confirming the heritability of aphid resistance in these selections.
